# Valais tourism organization

- Tourism sector in the canton of Valais is organized in 19 destinations management organization (DMO). Some of them are very well know, like the so called big five : Zermatt, Verbier, Leukerbad, Saastall et Crans-Montana.
- The canton is divided in three different regions: Bas Valais, Haut Valais and Valais Romand.
- The lowest level of aggregation for the overnights statistics is the town level.

# The research problem

Our task consists on the forecast of overnights.

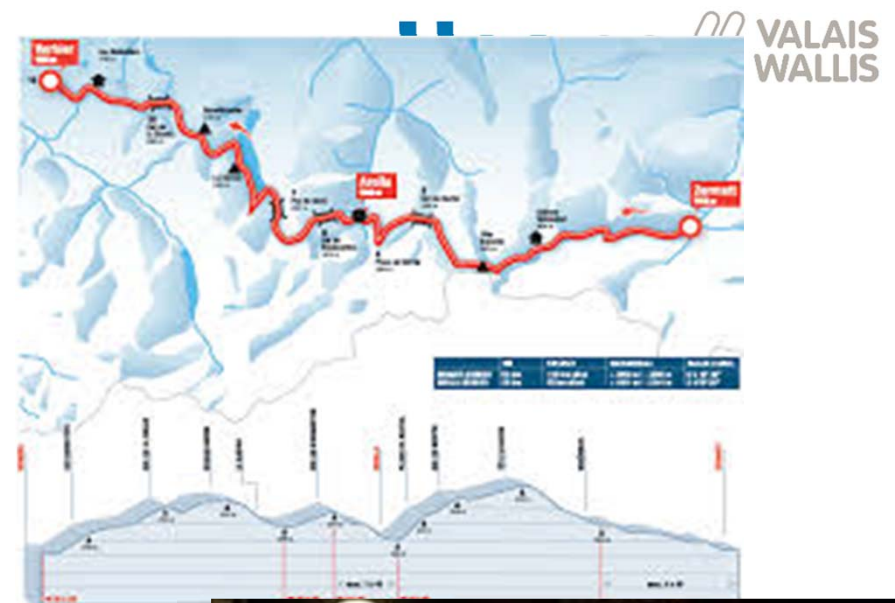

- The areas of forecast interests are aggregated levels such as destinations and cantonal level.
- The question is whether the use of the aggregated or hierarchical methods will yield better forecasting accuracy than the forecasting at the level of destinations and/or canton.

# Rationale of the research question (I)

Better representation of the impact on overnights of local events at the aggregated level (destination or towns).

Examples:

- Omega European Masters (golf)
- Patrouille de Glacier
- Verbier festival
- etc.

# Rationale of the research question (II)

Better representation behavior of the demand due to their taste or the schedule of their (winter) holidays.

Domestic market: two facts

The 26 cantons set school vacation independently but try to stagger them as much as possible.

1. There are **moving-holidays** as the date of beginning is linked to the end Carnival season.
2. It is not very clear which **ski resort is preferred by the different Swiss cantons**.

It is not possible or very complicated to treat this facts using intervention variables.

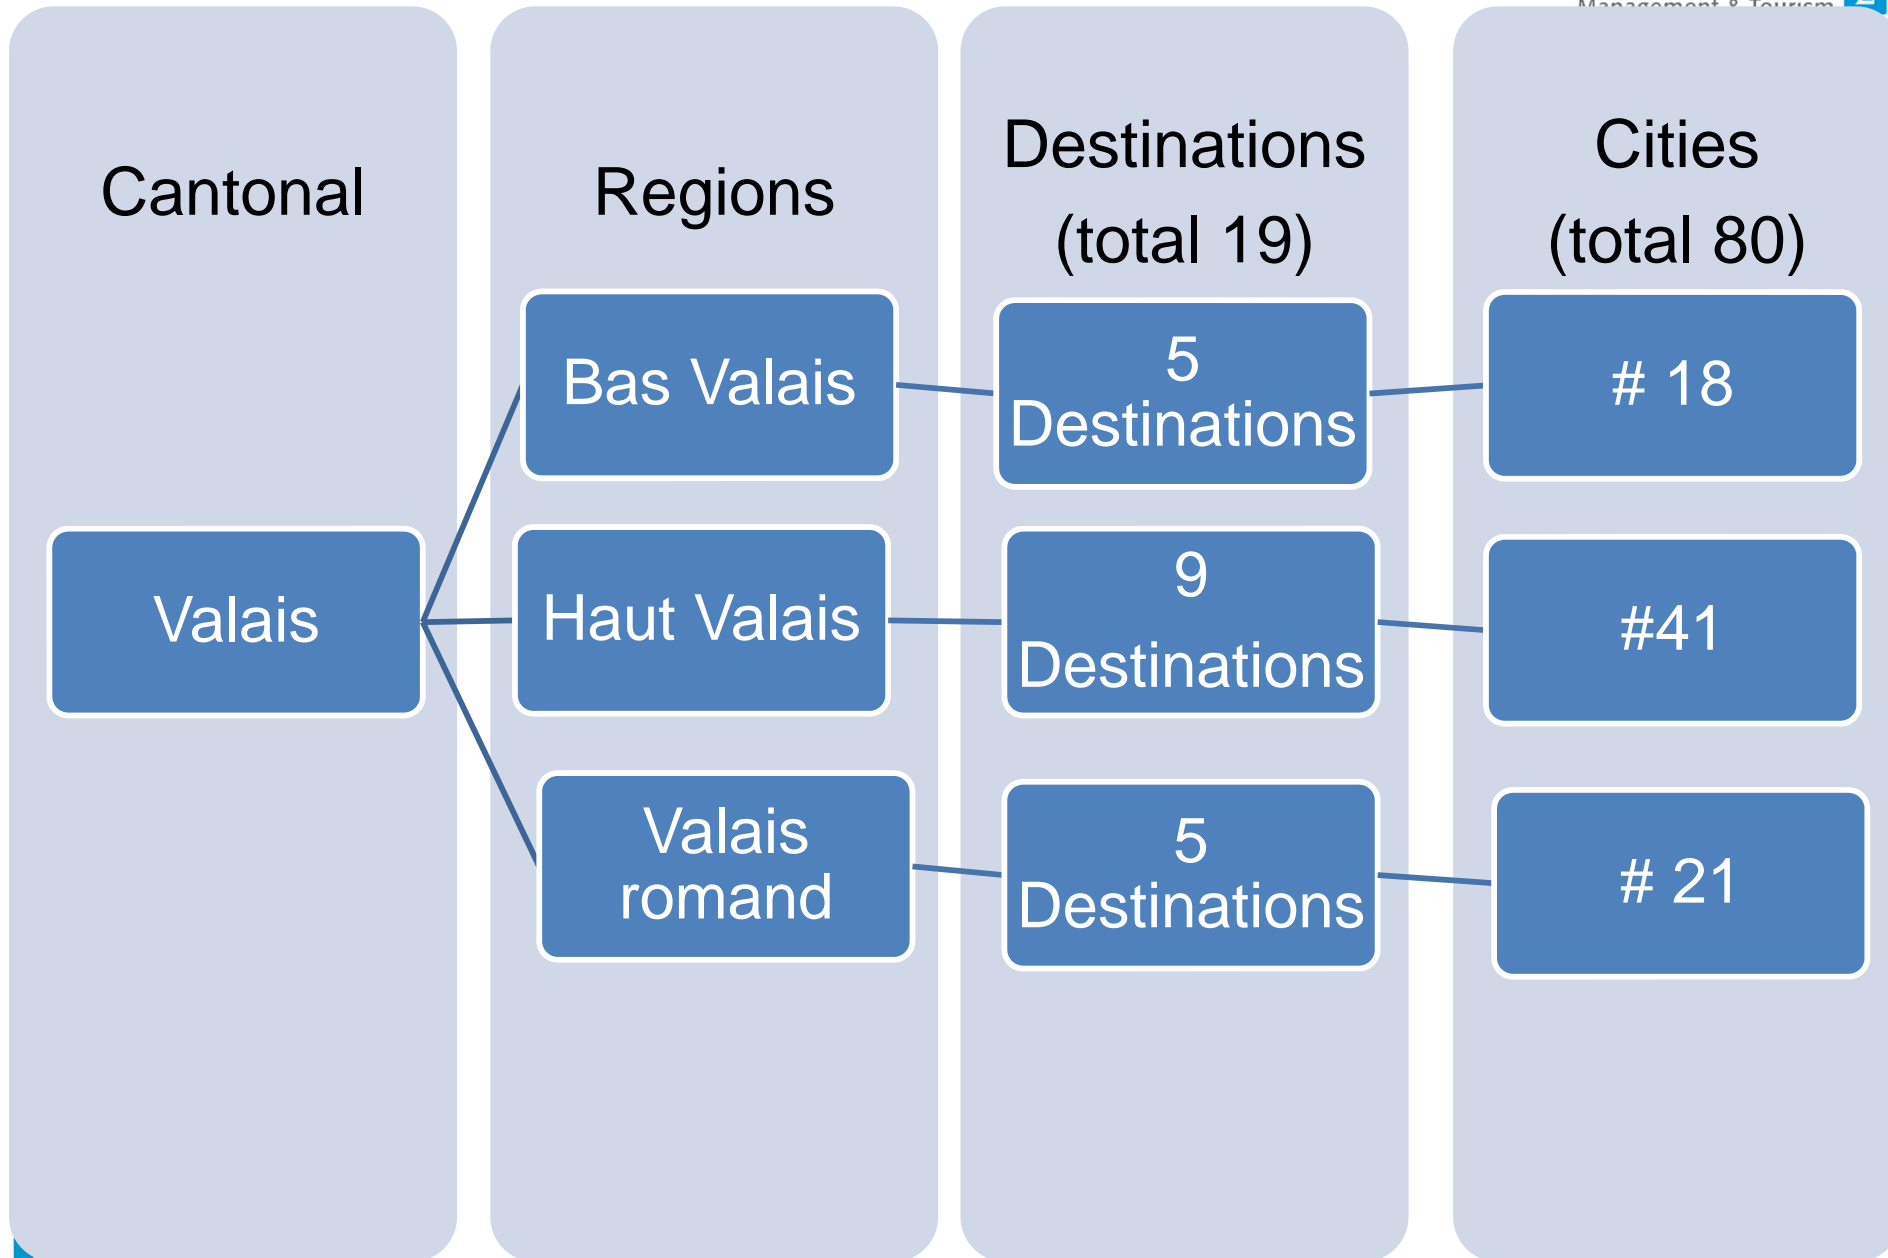

Up to some extent, the same considerations apply to the foreign demand.

# Research questions

The accuracy of the forecast can be affected by:

- The depth of the tree or hierarchy
- The kind of forecasting method (ARIMA, random walk or ets)
- The method used for reconciling the base forecasts (Optimal combination forecasts, bottom-up, top-down, combination, Middle-out forecasts).

# The data (I)

# The data (II)

- The source of the data is **Swiss Federal Statistical Office** in Neuchâtel
- The series are monthly and count Hotels' Overnights from January 2005 to March 2014, 111 observations.
- The series are download at the city level for the Valais. The numbers of series was greater than the final 80 used in this research. The authors had to aggregate some towns given their political merge during the period under study or for confidentiality issues.
- Finally the set is composed of 80 series of overnights at the city level.

# Methodology (I) : software

The software used is R's times series facilities, more specifically, the package hts (hierarchical time series).

## Details

R. J. Hyndman, R. A. Ahmed, G. Athanasopoulos and H.L. Shang (2011) Optimal combination forecasts for hierarchical time series. *Computational Statistics and Data Analysis*, **55**(9), 2579–2589. <http://robjhyndman.com/papers/hierarchical/>

<https://www.otexts.org/fpp/9/4>

As a benchmark the series at the aggregate level of canton, regions and destinations have been forecasted using Stamp software, using 2 intervention variables, one for Easter and the other for Ascension and Whitsunday.

# Methodology (II): hierarchies

Different trees or hierarchies having different depths (1, 2 and 3) were tested.

- 1. Full tree:** depth of the tree is 3 ( cf. slide “The data”); called model “Total”
- 2. Depth 2 :** Cantonal (root) ->destinations->cities; called model “destinations”; and  
Cantonal (root)->Region->cities ;  
called mode, “Regions”.
- 3. Depth 1:** Cantonal (root)->cities; called model “city”; .

# Methodology (III): forecasting model

The forecasting models used for the base forecasts are the ones allowed in R and the hts package.

1. Exponential smoothing state space model (ets)
2. ARIMA
3. Random walk (rw)

# Methodology (III): forecasting model (cont')

The models were run before the middle of June 2014 et re-run after that date.

Rob Hyndman has made a number of changes on the forecasting algorithms.

Moreover, in order to take into account the Easter and Ascension and Pentecost, two intervention variables, used in the benchmark estimation (STS) were included in the latter re-running process for ARIMA.

From hereafter, the earlier process will be named “Without” and the later “With”.

# Methodology (IV): reconciling methods for the base forecasts

We obtained 2'280 forecasts for each of the following conciliation methods, in total 13'348, for the benchmark only 103. The available methods in the hts package are the following :

1. Optimal combination forecasts (comb)
2. Bottom-up forecasts (bu)
3. Bottom-up forecasts Middle-out forecasts where the level used is specified by the level argument (mo)
4. Top-down forecasts based on the average historical proportions (Gross-Sohl method A) (tdgsa)
5. Top-down forecasts based on the proportion of historical averages (Gross-Sohl method F) (tdgsf)
6. Top-down forecasts using forecast proportions (tdfp).

# Methodology (V): Accuracy assessment

<p><b>RMSE</b> Root Mean Squared Error</p> $RMSE = \sqrt{\frac{1}{n} \sum_{t=1}^n (F_t - A_t)^2}$	<p><b>MAE</b> Mean Absolute Error</p> $MAE = \frac{1}{n} \sum_{t=1}^n  F_t - A_t $	<p><b>MAPE</b> Mean Absolute Percentage Error</p> $MAPE = \frac{\sum_{t=1}^n \left  \frac{A_t - F_t}{A_t} \right }{n} \times 100$
<p><b>MPE</b> Mean Percentage Error</p> $MPE = \frac{\sum_{t=1}^n \frac{A_t - F_t}{A_t}}{n} \times 100$	<p><b>MASE</b> Mean Absolute Scaled Error</p> $MASE = \frac{1}{n} \sum_{t=1}^n \left( \frac{ A_t - F_t }{\frac{1}{T-m} \sum_{i=m+1}^T  A_i - A_{i-m} } \right)$	

A scaled error is less than one if it arises from a better forecast than the average naïve forecast computed on the training data. Conversely, it is greater than one if the forecast is worse than the average naïve forecast computed on the training data.

# Methodology (VI): Error calculi

Except for the benchmark, all the errors were calculated using hts package.

For the benchmark, a customized routine was programmed in SAS Institute V9.4.

The graphs and tables of this presentation and the significant tests were calculated using Sphinx V5.

**Warning:** The ANOVA test has only an informatif value because the sample composed by hts methods and the benchmark is unbalanced (hts #13'348 vs STS #103)

# Accuracy leaves = towns

Errors Towns

Error measure

p = 0.0% ; chi2 = 411.45 ; dof = 6 (VS)

Arima outperforms all the others. But in general the performance is not as good as we would have liked to.

Arima and ets tend to overestimate (ME<0) whereas the contrary happens with RW and STS (ME>0).

# Conclusions

- At the lowest levels (towns), hts perform better than the benchmark.
- At the aggregate levels (regions, destinations and canton) the performances of hts and benchmark are comparable.
- ARIMA outperforms all the other forecast methods of the hts package and the worst seems to be RW.
- The conciliation methods seems to have some effect at the destination level, mo and comb are superior.

# Wishing list (I)

- The hts forecasting method could be quite interesting for tourism if the aim is to forecast at all the levels, from towns to the canton.
- If this is not the case, the benchmark is comparable with the results of hts with the economy of saving the data of the lowest levels.

# Wishing list (II)

- A real asset would be to be able to make assumption on the forecast of the trend at the lowest level in order to simulate/estimate the effect at the highest level.

For instance, a group planning a festival/event in a town could show the effect on overnight at the highest level (destination, region or canton). Also establish different scenarii using different methods of conciliation.

Thank very much!
